

Recruitment and fecundity of Minnesota moose

This project addresses a current knowledge gap: information on young moose (1-3 yrs old)

We propose to capture and collar juvenile moose during their first winter, when they are 8-9 months old and weigh about 400 lbs

If we are successful, we would greatly increase the amount of survival, reproduction, and habitat use data we have on these young moose

This data will contribute to population modeling, habitat management, and population management decisions by the MN DNR, tribes, and other agencies
